# METASPLOITABLE 2 VULNERABILITY SCAN RESULTS

| | |
|---|---|
| **Name of Individual Conducting Scanning:** | Abbhilash Simanchalam |
| **Nessus Scanner IP (IP of Kali VM):** | 192.168.28.135 |
| **Date & Time Scan Started:** | 19 April 2026, 3:09 AM |
| **Date & Time Scan Finished:** | 19 April 2026, 3:29 AM |
| **Security Issues Identified:** | Multiple critical and high severity vulnerabilities were identified, including backdoors, outdated services, insecure protocols, and weak configurations. |

**Overview:**

The vulnerability scan revealed that the Metasploitable 2 system is extremely vulnerable. Several critical vulnerabilities were discovered, including backdoor access, outdated operating system components, and insecure services. These vulnerabilities could allow attackers to gain unauthorized remote access, execute commands, and fully compromise the system. Immediate remediation is required to secure the system.

**Top 5 Most Serious Security Issues:**

**1. Most serious issue**
**UnrealIRCd Backdoor Detection**

**Description:**
The UnrealIRCd service contains a known backdoor that allows attackers to execute commands remotely without authentication.

**Impact:**
An attacker can gain remote shell access and take full control of the system.

---

**2. Security flaw**
**VNC Server 'password' Password**

**Description:**
The VNC service is configured with a weak default password (“password”), making it easy to guess.

**Impact:**
Attackers can gain unauthorized remote desktop access and control the system.

---

**3. Security flaw**
**Bind Shell Backdoor Detection**

**Description:**
A bind shell backdoor is present, allowing attackers to connect directly to the system and execute commands.

**Impact:**
This allows attackers to bypass authentication and gain direct control of the system.

---

**4. Security flaw**
**SSL Version 2 and 3 Protocol Detection**

**Description:**
The system supports outdated SSL protocols (SSLv2 and SSLv3), which are insecure and vulnerable to attacks.

**Impact:**
Attackers can exploit these protocols to intercept or decrypt sensitive communication.

---

**5. Security flaw**
**Samba Badlock Vulnerability**

**Description:**
The Samba service is vulnerable to the Badlock vulnerability, which allows man-in-the-middle attacks.

**Impact:**
Attackers can intercept, modify, or disrupt network communications.

**Top 5 – Remediations:**

**1. Most serious issue remediation**

**Remove or reinstall the UnrealIRCd service using a verified and secure version. Ensure no backdoors are present in the system.**

---

**2. Security flaw remediation**

**Change the VNC password to a strong, complex password and restrict access to trusted users only.**

---

**3. Security flaw remediation**

**Identify and remove any bind shell backdoors from the system and monitor for**

unauthorized open ports.

---

**4. Security flaw remediation**

Disable SSLv2 and SSLv3 protocols and upgrade to secure versions such as TLS 1.2 or TLS 1.3.

---

**5. Security flaw remediation**

Update the Samba service to a patched version and apply all relevant security updates.
